The two key markers for kidney disease are urine albumin and estimated glomerular filtration rate (eGFR). For patients with type 1 diabetes for 5 years or more or with type 2 diabetes, the American Diabetes Association and the National Kidney Disease Education Program (NKDEP) recommend that health care professionals:

- Assess urine albumin excretion yearly to diagnose and monitor kidney damage. More frequent monitoring may be indicated in patients with changing clinical status or after therapeutic interventions.
- Screen using a spot UACR. UACR estimates 24-hour urine albumin excretion. 24-hour collection and timed specimens are not necessary.

Reducing urine albumin to the normal or near-normal range may improve renal and cardiovascular prognoses.

\[
\frac{\text{Urine albumin (mg/dL)}}{\text{Urine creatinine (g/dL)}} = \text{UACR in mg/g} \approx \text{Albumin excretion in mg/day}
\]

UACR is a ratio between two measured substances. Unlike a dipstick test for albumin, it is unaffected by variation in urine concentration.

Interpreting UACR Results

<table>
<thead>
<tr>
<th>Albuminuria/Clinical Proteinuria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microalbuminuria</td>
</tr>
<tr>
<td>Kidney disease may be present when UACR is greater than 30 mg/g with or without decreased eGFR (see reverse side about eGFR).</td>
</tr>
<tr>
<td>Normal</td>
</tr>
</tbody>
</table>

If kidney disease is detected, it should be addressed as part of a comprehensive approach to the treatment of diabetes.

For more information on UACR and kidney disease, go to www.nkdep.nih.gov.

NKDEP, a program of the National Institutes of Health, aims to improve early detection of kidney disease, help identify patients at risk for progression to kidney failure, and promote interventions to slow progression of kidney disease.
Estimated Glomerular Filtration Rate (eGFR)

The two key markers for kidney disease are eGFR and urine albumin.

The American Diabetes Association and the National Kidney Disease Education Program (NKDEP) recommend that health care professionals:

- Calculate eGFR from stable serum creatinine levels at least once a year in all patients with diabetes.
  - eGFR is more accurate than serum creatinine alone. Serum creatinine is affected by muscle mass, and related factors of age, sex, and race.
  - eGFR is not reliable for patients with normal kidney function, rapidly changing creatinine levels, or extremes in muscle mass and diet, e.g., very muscular or large people, cachectic people, and vegans.

See if your lab reports eGFR routinely or if you need to request it. GFR calculators are available on NKDEP’s website at www.nkdep.nih.gov.

### Interpreting eGFR Results

NKDEP recommends reporting values greater than or equal to 60 as “≥60,” rather than numeric values. Exact values above 60 are not reliable.

<table>
<thead>
<tr>
<th>eGFR (ml/min/1.73 m²)</th>
<th>Kidney Disease</th>
</tr>
</thead>
<tbody>
<tr>
<td>≥60</td>
<td>Kidney disease may be present when eGFR is less than 60 ml/min/1.73 m², or if UACR exceeds 30 mg/g (see reverse side about UACR).</td>
</tr>
<tr>
<td>15</td>
<td>Kidney Failure</td>
</tr>
</tbody>
</table>

If kidney disease is detected, it should be addressed as part of a comprehensive approach to the treatment of diabetes.

For more information on eGFR and kidney disease, go to www.nkdep.nih.gov.

NKDEP, a program of the National Institutes of Health, aims to improve early detection of kidney disease, help identify patients at risk for progression to kidney failure, and promote interventions to slow progression of kidney disease.
